

- LLM prompt for code generation
- Create a python function to do the following:
- Into a dataframe load the file 'newtons-law-time-distance-data-MLR.csv'
 - The dependent variable is 'y', all others are independent variables
 - Divide the data into train / test (80:20)
 - Show scatter plots of the train and test data (in a single row)
 - Train a regression model using LinearRegression from sklearn
 - Print the following information:
 - Regression outputs
 - Create the following plots for train and test data - using 2 plots in each row:
 - Predicted values superimposed over actual values of the dependent variable v/s the first independent variable
 - Residuals v/s the first independent variable
 - Histograms of residuals
 - QQ Plots of residuals
- Perform similar steps, but now using OLS from statsmodels
